RFC 9456

Updates to the TLS Transport Model for SNMP

Abstract

This document updates RFC 6353 ("Transport Layer Security (TLS) Transport Model for the Simple Network Management Protocol (SNMP)") to reflect changes necessary to support Transport Layer Security version 1.3 (TLS 1.3) and Datagram Transport Layer Security version 1.3 (DTLS 1.3), which are jointly known as "(D)TLS 1.3". This document is compatible with (D)TLS 1.2 and is intended to be compatible with future versions of SNMP and (D)TLS.

This document updates the SNMP-TLS-TM-MIB as defined in RFC 6353.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <https://www.rfc-editor.org/info/rfc9456>.

Copyright Notice

1. Introduction

This document updates and clarifies how the rules of [\[RFC6353\]](#) apply when using Transport Layer Security (TLS) or Datagram Transport Layer Security (DTLS) versions later than 1.2. This document jointly refers to these two protocols as "(D)TLS". The update also emphasizes the requirement in [\[RFC8996\]](#) prohibiting the use of TLS versions prior to TLS 1.2 [\[RFC5246\]](#) when

using SNMP. Although the text of this document specifically references SNMPv3 and (D)TLS 1.3, this document may be applicable to future versions of these protocols and is backwards compatible with (D)TLS 1.2.

1.1. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to [Section 7](#) of [\[RFC3410\]](#).

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIV2, which is described in RFCs 2578, 2579, and 2580 [\[STD58\]](#).

1.2. Conventions

Within this document, the terms "TLS", "DTLS", and "(D)TLS" apply to all versions of the indicated protocols. The term "SNMP" means "SNMPv3" unless a specific version number is indicated. Specific version numbers are used when the text needs to emphasize version numbers.

For consistency with SNMP-related specifications, this document favors terminology as defined in [\[STD62\]](#), rather than favoring terminology that is consistent with non-SNMP specifications. This is consistent with the IESG decision to not require that the SNMP terminology be modified to match the usage of other non-SNMP specifications when SNMP was advanced to an Internet Standard. "Authentication" in this document typically refers to the English meaning of "serving to prove the authenticity of" the message, not data source authentication or peer identity authentication. The terms "manager" and "agent" are not used in this document because, in the architecture defined in RFC 3411 [\[STD62\]](#), all SNMP entities have the capability of acting as manager, agent, or both, depending on the SNMP application types supported in the implementation. Where distinction is necessary, the application names of command generator, command responder, notification originator, notification receiver, and proxy forwarder are used. See "An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks" (RFC 3411 [\[STD62\]](#)) for further information.

Throughout this document, the terms "client" and "server" are used to refer to the two ends of the TLS transport connection. The client actively opens the TLS connection, and the server passively listens for the incoming TLS connection. An SNMP entity **MAY** act as a TLS client, TLS server, or both, depending on the SNMP applications supported.

Throughout this document, the term "session" is used to refer to a secure association between two instances of the TLS Transport Model (TLSTM) that permits the transmission of one or more SNMP messages within the lifetime of the session. The TLS protocol also has an internal notion of a session, and although these two concepts of a session are related, when the term "session" is used, this document is referring to the TLSTM's specific session and not directly to the TLS protocol's session.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2. Changes from RFC 6353

This document updates [RFC6353]. The changes from [RFC6353] are defined in the following subsections.

2.1. TLSTM Fingerprint

[RFC6353] defines the SnpmtlsFingerprint textual convention to include the one-octet TLS 1.2 hash algorithm identifier. This one-octet algorithm identifier is only applicable to (D)TLS protocol versions prior to 1.3. The TLS community does not plan to ever add additional values to the "TLS HashAlgorithm" registry [RFC5246], because some might incorrectly infer that using a new hash algorithm with TLS 1.2 would overcome the limitations of TLS 1.2. However, there is still a need within TLSTM to support new values as they are developed.

This document updates the definition of SnpmtlsFingerprint to clarify that the one-octet algorithm identifier uses the values in the IANA "SNMP-TLSTM HashAlgorithms" registry; this registry is consistent with the IANA "TLS HashAlgorithm" registry for its initial values but can be extended as needed to support new hashing algorithms without implying that the new values can be used by TLS version 1.2. This change allows the reuse of the existing fingerprint textual convention and minimizes the impact to [RFC6353].

A "Y" in the "Recommended" column (Table 1) indicates that the registered value has been recommended through a formal Standards Action [RFC8126]. Not all parameters defined in Standards Track documents are necessarily marked as "Recommended".

An "N" in the "Recommended" column does not necessarily mean that the value is flawed; rather, it indicates that the item either has not been through the IETF consensus process, has limited applicability, or is intended only for specific use cases.

The initial values for the "SNMP-TLSTM HashAlgorithms" registry are defined below:

Value	Description	Recommended	References
0	none	N	[RFC5246]
1	md5	N	[RFC5246]
2	sha1	N	[RFC5246]
3	sha224	Y	[RFC5246]
4	sha256	Y	[RFC5246]

Value	Description	Recommended	References
5	sha384	Y	[RFC5246]
6	sha512	Y	[RFC5246]
7	Reserved		[RFC8447]
8	Intrinsic	N	[RFC8422]
9-223	Unassigned		
224-255	Reserved for Private Use		[RFC5246]

Table 1: SNMP-TLSTM Hash Algorithms

Values 0 through 2 **MUST NOT** be used by implementations of this document but are listed for historical consistency.

2.2. Security Level

The architecture defined in RFC 3411 [STD62] recognizes three levels of security:

- without authentication and without privacy (noAuthNoPriv)
- with authentication but without privacy (authNoPriv)
- with authentication and with privacy (authPriv)

Cipher suites for (D)TLS 1.3 defined in [RFC8446] provide both authentication and privacy. Cipher suites defined in [RFC9150] for (D)TLS 1.3 provide only authentication, without any privacy protection. Implementations **MAY** choose to force (D)TLS 1.3 to only allow cipher suites that provide both authentication and privacy.

2.3. (D)TLS Version

[RFC6353] states that TLSTM clients and servers **MUST NOT** request, offer, or use SSL 2.0.

[RFC8996] prohibits the use of (D)TLS versions prior to version 1.2. TLSTM **MUST** only be used with (D)TLS versions 1.2 and later.

3. Additional Rules for TLS 1.3

This document specifies additional rules and clarifications for the use of TLS 1.3. These rules may additionally apply to future versions of TLS.

3.1. Zero Round-Trip Time Resumption (0-RTT)

TLS 1.3 implementations for SNMP **MUST NOT** enable the 0-RTT mode of session resumption (either sending or accepting) and **MUST NOT** automatically resend 0-RTT data if it is rejected by the server. 0-RTT is disallowed because there are no "safe" SNMP messages that, if replayed, will

be guaranteed to cause no harm at the server side: all incoming notifications or command responses are meant to be acted upon only once. See [Section 5](#) ("[Security Considerations](#)") for further details.

TLSTM clients and servers **MUST NOT** request, offer, or use the 0-RTT mode of TLS 1.3. [\[RFC8446\]](#) removed the renegotiation supported in TLS 1.2 [\[RFC5246\]](#); for session resumption, it introduced a zero-RTT (0-RTT) mode, saving a round trip at connection setup at the cost of increased risk of replay attacks (it is possible for servers to guard against this attack by keeping track of all the messages received). [\[RFC8446\]](#) requires that a profile be written for any application that wants to use 0-RTT, specifying which messages are "safe to use" with this mode. Within SNMP, there are no messages that are "safe to use" with this mode.

Renegotiation of sessions is not supported, as it is not supported by TLS 1.3. If a future version of TLS supports renegotiation, this RFC should be updated to indicate whether there are any additional requirements related to its use.

3.2. TLS Cipher Suites, Extensions, and Protocol Invariants

[Section 9](#) of [\[RFC8446\]](#) requires that, in the absence of application profiles, certain cipher suites, TLS extensions, and TLS protocol invariants be mandatory to implement. This document does not specify an application profile; hence, all the compliance requirements in [\[RFC8446\]](#) apply.

4. MIB Module Definitions

This SNMP-TLS-TM-MIB module imports items from RFCs 2578, 2579, and 2580 [\[STD58\]](#), as well as RFCs 3411 and 3413 [\[STD62\]](#). It also references [\[RFC1123\]](#), [\[RFC5246\]](#), [\[RFC5280\]](#), [\[RFC5591\]](#), [\[RFC5890\]](#), [\[RFC5952\]](#), [\[RFC5953\]](#), [\[RFC6353\]](#), and RFC 2579 [\[STD58\]](#).

to, and subject to the license terms contained in,
the Revised BSD License set forth in Section 4.c
of the IETF Trust's Legal Provisions Relating to IETF
Documents (<https://trustee.ietf.org/license-info>).

The key words 'MUST', 'MUST NOT', 'REQUIRED', 'SHALL',
'SHALL NOT', 'SHOULD', 'SHOULD NOT', 'RECOMMENDED',
'NOT RECOMMENDED', 'MAY', and 'OPTIONAL' in this document
are to be interpreted as described in BCP 14 (RFC 2119)
(RFC 8174) when, and only when, they appear in all
capitals, as shown here."

REVISION "202311080000Z"

DESCRIPTION

"This version of this MIB module is part of
RFC 9456; see the RFC itself for full legal
notices. This version does the following:

- 1) Updates the definition of SnmpTLSFingerprint
to clarify the registry used for the one-octet
hash algorithm identifier.
- 2) Capitalizes key words in conformance with
BCP 14.
- 3) Replaces 'may not' with 'MUST NOT' to clarify
intent in several locations.
- 4) Replaces 'may not' with a clarification within
the definition of SnmpTLSAddress.
- 5) Applies cosmetic grammar improvements and
reformatting causing whitespace changes."

REVISION "201107190000Z"

DESCRIPTION

"This version of this MIB module is part of
RFC 6353; see the RFC itself for full legal
notices. The only change was to introduce
new wording to reflect required changes for
Internationalized Domain Names for Applications
(IDNA) addresses in the SnmpTLSAddress textual
convention (TC)."

```

        for SMIV2"
    ::= { snmpDomains 9 }

```

```
SnmpTLSAddress ::= TEXTUAL-CONVENTION
  DISPLAY-HINT "1a"
  STATUS      current
  DESCRIPTION
    "Represents an IPv4 address, an IPv6 address, or an
     ASCII-encoded host name and port number.

    An IPv4 address MUST be in dotted decimal format followed
    by a colon ':' (ASCII character 0x3A) and a decimal
    port number in ASCII.

    An IPv6 address MUST be a colon-separated format (as
    described in RFC 5952), surrounded by square brackets
    ('[', ASCII character 0x5B, and ']', ASCII character
    0x5D), followed by a colon ':' (ASCII character 0x3A)
    and a decimal port number in ASCII.

    A host name MUST be in ASCII (as per RFC 1123);
    internationalized host names MUST be encoded as A-labels as
    specified in RFC 5890. The host name is followed by a
    colon ':' (ASCII character 0x3A) and a decimal port
    number in ASCII. The name SHOULD be fully qualified
    whenever possible.

    Values of this textual convention are not guaranteed to be
    directly usable as transport-layer addressing information,
    potentially requiring additional processing, such as
    run-time resolution. As such, applications that write
    them MUST be prepared for handling errors if such values
    are not supported or cannot be resolved (if resolution
    occurs at the time of the management operation).

    The DESCRIPTION clause of TransportAddress objects that
    may have SnmpTLSAddress values MUST fully describe how
    (and when) such names are to be resolved to IP addresses
    and vice versa.

    This textual convention SHOULD NOT be used directly in
    object definitions, since it restricts addresses to a
    specific format. However, if it is used, it MAY be used
    either on its own or in conjunction with
    TransportAddressType or TransportDomain as a pair.

    When this textual convention is used as a syntax of an
    index object, there may be issues with the limit of 128
    sub-identifiers specified in SMIv2 (STD 58). It is
    RECOMMENDED that all MIB documents using this textual
    convention make explicit any limitations on index
    component lengths that management software MUST observe.
    This MAY be done by either 1) including SIZE constraints
    on the index components or 2) specifying applicable
    constraints in the conceptual row's DESCRIPTION clause or
    in the surrounding documentation."

RFC 5952: A Recommendation for IPv6 Address Text
Representation"
SYNTAX      OCTET STRING (SIZE (1..255))

SnmpTLSTSFingerprint ::= TEXTUAL-CONVENTION
  DISPLAY-HINT "1x:1x"
  STATUS      current
  DESCRIPTION
    "A fingerprint value that can be used to uniquely reference
    other data of potentially arbitrary length.

    An SnmpTLSTSFingerprint value is composed of a one-octet
    hashing algorithm identifier followed by the fingerprint
    value. The one-octet identifier value encoded is taken
    from the IANA 'SNMP-TLSTM HashAlgorithms' registry. The
    remaining octets of the SnmpTLSTSFingerprint value are
    filled using the results of the hashing algorithm.

    Historically, the one-octet hashing algorithm identifier
    was based on the IANA 'TLS HashAlgorithm' registry
    (RFC 5246); however, this registry is no longer in use for
    TLS 1.3 and above and is not expected to have any new
    registrations added to it. To allow the fingerprint
    algorithm to support additional hashing algorithms that
    might be used by later versions of (D)TLS, the octet value
    encoded is now taken from the IANA
    'SNMP-TLSTM HashAlgorithms' registry. The initial values
    within this registry are identical to the values in the
    'TLS HashAlgorithm' registry but can be extended to
    support new hashing algorithms as needed.

    This textual convention allows for a zero-length (blank)
    SnmpTLSTSFingerprint value for use in tables where the
    fingerprint value MAY be optional. MIB definitions or
    implementations MAY refuse to accept a zero-length value
    as appropriate."

    Certificate and Certificate Revocation
    List (CRL) Profile"
    ::= { snmpTlstmCertToTSNMIdentities 3 }

snmpTlstmCertSANIpAddress OBJECT-IDENTITY
  STATUS      current
  DESCRIPTION
    "Maps a subjectAltName's iPAddress to a tmSecurityName by
    transforming the binary-encoded address as follows:

    1) For IPv4, the value is converted into a
    decimal-dotted quad address (e.g., '192.0.2.1').

    2) For IPv6 addresses, the value is converted into a
    32-character all-lowercase hexadecimal string
    without any colon separators.

    This mapping results in a 1:1 correspondence between
    subjectAltName iPAddress values and the tmSecurityName
    values.

    The resulting length of an encoded IPv6 address is the
    maximum length supported by the View-based Access Control
    Model (VACM). Using an IPv6 address while the value of
    snmpTsmConfigurationUsePrefix is 'true' (see the
    SNMP-TSM-MIB, as defined in RFC 5591) will result in
    securityName lengths that exceed what the VACM can handle."

snmpTlstmCertSANAny OBJECT-IDENTITY
    STATUS      current
    DESCRIPTION
        "Maps any of the following fields using the corresponding
        mapping algorithms:

            +-----+-----+
            | Type      | Algorithm |
            +-----+-----+
            | rfc822Name | snmpTlstmCertSANRFC822Name |
            | dNSName    | snmpTlstmCertSANDNSName   |
            | iPAddress  | snmpTlstmCertSANIpAddress |
            +-----+-----+

        The first subjectAltName value contained in the certificate
        that matches any of the above types MUST be used when
        deriving the tmSecurityName. The mapping algorithm
        specified in the 'Algorithm' column of the corresponding
        row MUST be used to derive the tmSecurityName.

        This mapping results in a 1:1 correspondence between
        subjectAltName values and tmSecurityName values. The
        three sub-mapping algorithms produced by this combined
        algorithm cannot produce conflicting results between
        themselves."

```
snmpTlstmCertToTSNTable OBJECT-TYPE
    SYNTAX      SEQUENCE OF SnmpTlstmCertToTSNEntry
    MAX-ACCESS  not-accessible
    STATUS      current
    DESCRIPTION
        "This table is used by a (D)TLS server to map the (D)TLS
        client's presented X.509 certificate to a tmSecurityName.

        On an incoming (D)TLS/SNMP connection, the client's
        presented certificate either MUST be validated based on an
        established trust anchor or MUST directly match a
        fingerprint in this table. This table does not provide
        any mechanisms for configuring the trust anchors; the
        transfer of any needed trusted certificates for path
        validation is expected to occur through an out-of-band
        transfer.

        Once the certificate has been found acceptable (either via
        path validation or by directly matching a fingerprint in
        this table), this table is consulted to determine the
        appropriate tmSecurityName to identify with the remote
        connection. This is done by considering each active row
        from this table in prioritized order according to its
        snmpTlstmCertToTSNID value. Each row's
        snmpTlstmCertToTSNFingerprint value determines whether the
        row is a match for the incoming connection:

        1) If the row's snmpTlstmCertToTSNFingerprint value
           identifies the presented certificate, then consider
           the row as a successful match.

        2) If the row's snmpTlstmCertToTSNFingerprint value
           identifies a locally held copy of a trusted CA
           certificate and that CA certificate was used to
           validate the path to the presented certificate, then
           consider the row as a successful match.

        Once a matching row has been found, the
        snmpTlstmCertToTSNMapType value can be used to determine
        how the tmSecurityName to associate with the session
        should be determined. See the 'snmpTlstmCertToTSNMapType'
        column's DESCRIPTION clause for details on determining the
        tmSecurityName value. If it is impossible to determine a
        tmSecurityName from the row's data combined with the data
        presented in the certificate, then additional rows MUST be
        searched to look for another potential match. If a
        resulting tmSecurityName mapped from a given row is not
        compatible with the needed requirements of a
```

tmSecurityName (e.g., the VACM imposes a 32-octet-maximum length and the certificate-derived securityName could be longer), then it MUST be considered an invalid match and additional rows MUST be searched to look for another potential match.

If no matching and valid row can be found, the connection MUST be closed and SNMP messages MUST NOT be accepted over it.

Missing values of snmpTlstmCertToTSNID are acceptable, and implementations SHOULD continue to the next-highest-numbered row. It is RECOMMENDED that administrators skip index values to leave room for the insertion of future rows (for example, use values of 10 and 20 when creating initial rows).

Users are encouraged to make use of certificates with subjectAltName fields that can be used as tmSecurityNames. This allows all child certificates of a single root CA certificate to include a subjectAltName that maps directly to a tmSecurityName via a 1:1 transformation. However, this table is flexible, to allow for situations where existing deployed certificate infrastructures do not provide adequate subjectAltName values for use as tmSecurityNames. Certificates MAY also be mapped to tmSecurityNames using the CommonName portion of the Subject field. However, the usage of the CommonName field is deprecated, and thus this usage is NOT RECOMMENDED. Direct mapping from each individual certificate fingerprint to a tmSecurityName is also possible but requires one entry in the table per tmSecurityName and requires more management operations to completely configure a device."

snmpTlstmAddrTable OBJECT-TYPE
```

SYNTAX SEQUENCE OF SnmpTlstmAddrEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION

"This table is used by a (D)TLS client when a (D)TLS connection is being set up using an entry in the SNMP-TARGET-MIB. It extends the SNMP-TARGET-MIB's snmpTargetAddrTable so that the client can verify that the correct server has been reached. This verification can use either 1) a certificate fingerprint or 2) an identity authenticated via certification path validation.

If there is an active row in this table corresponding to the entry in the SNMP-TARGET-MIB that was used to establish the connection and the row's 'snmpTlstmAddrServerFingerprint' column has a non-empty value, then the server's presented certificate is compared with the snmpTlstmAddrServerFingerprint value (and the 'snmpTlstmAddrServerIdentity' column is ignored). If the fingerprint matches, the verification has succeeded. If the fingerprint does not match, then the connection MUST be closed.

If the server's presented certificate has passed certification path validation (RFC 5280) to a configured trust anchor and an active row exists with a zero-length snmpTlstmAddrServerFingerprint value, then the 'snmpTlstmAddrServerIdentity' column contains the expected host name. This expected host name is then compared against the server's certificate as follows:

- Implementations MUST support matching the expected host name against a dNSName in the subjectAltName extension field and MAY support checking the name against the CommonName portion of the subject distinguished name.
- The '*' (ASCII 0x2A) wildcard character is allowed in the dNSName of the subjectAltName extension (and in CommonName, if used to store the host name), but only as the leftmost (least significant) DNS label in that value. This wildcard matches any leftmost DNS label in the server name. That is, the subject *.example.com matches the server names a.example.com and b.example.com but does not match example.com or a.b.example.com. Implementations MUST support wildcards in certificates as specified above but MAY provide a configuration option to disable them.
- If the locally configured name is an internationalized domain name, conforming implementations MUST convert it to the ASCII Compatible Encoding (ACE) format for performing comparisons, as specified in Section 7 of RFC 5280.

If the expected host name fails these conditions, then the connection MUST be closed.

If there is no row in this table corresponding to the entry in the SNMP-TARGET-MIB and the server can be authorized by another, implementation-dependent means, then the connection MAY still proceed."

5. Security Considerations

This document updates a transport model that permits SNMP to utilize (D)TLS security services. The security threats and how the TLSTM mitigates these threats are covered throughout this document and in [RFC6353]. Security considerations for TLS are described in Section 10 and Appendix E of TLS 1.3 [RFC8446]. Security considerations for DTLS are described in Section 11 of DTLS 1.3 [RFC9147].

Implementations should consider the latest recommendations on the use of (DTLS), such as those documented in [RFC9325].

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example, by using IPsec), there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is **RECOMMENDED** that only SNMPv3 messages using the Transport Security Model (TSM) or another secure-transport-aware security model be sent over the TLSTM transport.

6. IANA Considerations

IANA has created a new registry called "SNMP-TLSTM HashAlgorithms" within the "Structure of Management Information (SMI) Numbers (MIB Module Registrations)" group. The description of this registry is "iso.org.dod.internet.mgmt.mib-2.snmpTlstmMIB.snmpTlstmHashAlgorithms (1.3.6.1.2.1.198.4)".

The registry has the following fields: Value, Description, Recommended, and References. The range of values is zero to 255, with initial assignments shown in Section 2.1. The "Recommended" column indicates "Y" for hashing algorithms that are Standards Track and are deemed to be acceptable for widely applicable current use and "N" for hashing algorithms that reflect meanings that are not recommended (e.g., they do not provide sufficient security for modern systems, they are not Standards Track, and they have limited applicability). A blank field indicates that no recommendation is made (e.g., because the value is unassigned or left for private use).

This registry is expected to be updated infrequently; as such, its values are limited to one octet.

The policy for updates to the "SNMP-TLSTM HashAlgorithms" registry is Expert Review [RFC8126]. Registry requests should be sent to the <<mailto:snmp-tlstm-reg-review@ietf.org>> mailing list. Registration requests sent to the mailing list for review **SHOULD** use an appropriate

subject (e.g., 'Request to register value in "SNMP-TLSTM HashAlgorithms" registry'). In addition, designated experts should consult with the <<mailto:tls-reg-review@ietf.org>> mailing list to make sure that any new hash algorithms are considered for inclusion in this registry.

Designated experts **SHOULD** ascertain the existence of suitable documentation that defines a hash algorithm and **SHOULD** also verify that the request does not conflict with or duplicate other entries in the registry. The experts should also provide a recommendation as to how the "Recommended" column of the registry should be updated. Only publicly available specifications that represent current industry-accepted practices should receive an assignment of "Y" in the "Recommended" column; all other specific assignments in the registry should receive an assignment of "N". Assignments that are nonspecific (e.g., reserved values) **SHOULD NOT** receive an assigned value for the "Recommended" column.

Within the three-week review period, the designated experts will either approve or deny the registration request, communicating this decision to the review list and IANA. Denials **SHOULD** include an explanation and, if applicable, suggestions as to how to make the request successful. Registration requests that are undetermined for a period longer than three weeks can be brought to the IESG's attention (using the <<mailto:iesg@ietf.org>> mailing list) for resolution.

IANA **MUST** only accept registry updates from the designated experts and **SHOULD** direct all requests for registration to the review mailing list. While future additions to the "TLS HashAlgorithm" registry (i.e., the registry from which the "SNMP-TLSTM HashAlgorithms" registry was spawned) are not expected, any future additions to the "TLS HashAlgorithm" registry **MUST** be consistent with the values assigned in the "SNMP-TLSTM HashAlgorithms" registry.

It is suggested that multiple designated experts be appointed who are able to represent the perspectives of different applications using this specification, in order to enable broadly informed reviews of registration decisions. In cases where a registration decision could be perceived as creating a conflict of interest for a particular expert, that expert **SHOULD** defer to the judgment of the other experts.
